Introduction to Exponents

When children study mathematics in primary school, they learn that repetitive addition, such as $3 + 3 + 3 + 3 + 3$, is the same as the multiplication $5 \times 3$.

There are occasions when repetitive multiplication occurs. To write this in a simpler way, the concept of exponents was developed. A study of exponents also helps students have a greater understanding of the number system used.

A very large number which fascinates mathematicians is the Googol. The Googol is written as:

$10^{100}$

This is equivalent to $10 \times 10 \times 10 \times \ldots \times 10$ for 100 terms.

Using exponents, a short-hand way of writing this is $10^{100}$.

While this number is beyond the comprehension of most people, other very large numbers such as the number of atoms in a quantity of material or the distance across the universe are still extremely large and very difficult to write in standard form. The same could be said extremely small numbers such as the diameter of an atom. An understanding of exponents gives us a more convenient way of writing both very large and very small numbers.

The first part of this module gives a thorough understanding of exponents leading to Scientific Notation which is used to represent numbers that are very large or extremely small.

Examples of repetitive multiplication are:

- $3 \times 3 \times 3 \times 3 \times 3$ is written in exponential form as $3^5$
- $4 \times 4 \times 4 \times 4 \times 4 \times 4 \times 4$ is written in exponential form as $4^9$
- $x \times x \times x \times x \times x \times x$ is written in exponential form as $x^6$
- $2a \times 2a \times 2a$ is written in exponential form as $(2a)^3$

It is important that brackets are used in this example to show that both the 2 and the $a$ are being repeated three times.
The Language of Exponents

The power $a^n$ can be written in expanded form as: $a^n = a \times a \times a \times a \times a \times a \times a \ldots \times a$ \[
\text{[for } n \text{ factors]} \]

The power $a^n$ consists of a base $a$ and an exponent (or index) $n$.

Saying Powers

$3^5$ can be said as ‘3 to the power of 5’, ‘3 to the 5th power’, ‘3 to the 5th’ or ‘3 raised to 5’. $4^9$ can be said as ‘4 to the power of 9’, ‘4 to the 9th power’, ‘4 to the 9th’ or ‘4 raised to 9’.

With common exponents such as 2 and 3, special language is used.

$8^2$ is most commonly said as 8 squared.

$5^3$ is most commonly said as 5 cubed.

$(2a)^3$ is said as ‘2a all cubed’ to emphasize that both the 2 and the a are being cubed.

Powers containing numbers can be evaluated.

$3^5 = 3 \times 3 \times 3 \times 3 \times 3 = 243$

Watch out! Many students will perform the multiplication $3 \times 5 = 15$ which is incorrect.

$2^7 = 2 \times 2 \times 2 \times 2 \times 2 \times 2 \times 2 = 128$

$(2.35)^4 = 2.35 \times 2.35 \times 2.35 \times 2.35 = 30.498$ (to 3 decimal places)
\[(3a)^3 = 3a \times 3a \times 3a = 27a^3\]

Be careful with negative numbers!

\[
(-4)^6 = -4 \times -4 \times -4 \times -4 \times -4 \times -4 = 4096
\]

When solving \(-4^6\), use the order of operation rules where the powers are performed before the multiplication.

\[-4^6 = -1 \times 4^6 = -1 \times 4096 = -4096\]

\[(-2)^4 = -2 \times -2 \times -2 \times -2 = 16\]

\[-2^4 = -1 \times 2^4 = -1 \times 16 = -16\]

**Powers containing variable bases can be expanded**

\[x^4 = x \times x \times x \times x\]

\[ab^3 = a \times b \times b \times b\]

\[(ab)^4 = ab \times ab \times ab \times ab = a \times a \times a \times a \times b \times b \times b \times b\]

One last thing to note: when a variable does not appear to have an exponent, the exponent is 1.

\[a = a^1\]

\[x = x^1\]

\[de = (de)^1\text{ or }d^1e^1\]

Topic 1: Exponent rules - whole number exponents

The product rule

To help develop the rule, let’s consider the question below:

\[2^5 \times 2^4\]

\[= (2 \times 2 \times 2 \times 2 \times 2) \times (2 \times 2 \times 2 \times 2)\]

altogether gives 9 factors

\[= 2 \times 2 \times 2 \times 2 \times 2 \times 2 \times 2 \times 2 \times 2\]

\[= 2^9\]

Generalising this:

\[a^m \times a^n = a^{m+n}\]

(When multiplying two powers with the same base, add the exponents.)

The quotient rule

To help develop the rule, let’s consider the question below:

\[ 2^7 \div 2^4 \]

\[ = \frac{2^7}{2^4} \leftarrow \text{write in fraction form} \]

\[ = \frac{2 \times 2 \times 2 \times \cancel{2^1} \times \cancel{2^1} \times \cancel{2^1} \times \cancel{2^1}}{\cancel{2^1} \times \cancel{2^1} \times \cancel{2^1} \times \cancel{2^1}} \leftarrow \text{simplify factors} \]

\[ = 2^3 \]

Generalising this:

\[ a^m \div a^n = a^{m-n} \]

(When dividing two powers with the same base, subtract the exponents.)

Zero exponent rule

To help develop the rule, let’s consider the question below where the solution is obtained by exponents and by evaluating the exponents:

\[
\frac{2^5}{2^5} \quad 2^5 \div 2^5
\]

\[
= \frac{2^5}{2^5} \quad = \frac{2^5}{2^5}
\]

or alternatively

\[
= 2^{5-5} \quad = \frac{2^5}{2^5}
\]

means that \(2^0 = 1\)

Generalising this for many different examples gives:

\[
\boxed{a^0 = 1}
\]

(A power with a zero exponent is equal to 1.)

Examples:

\[
5^0 = 1 \quad (-3)^0 = 1 \quad p^5 \times p^0 \quad = p^5 \times 1 \quad = p^5
\]

\[
(5a)^0 = 1 \quad 5a^0 \quad = 5 \times 1 \quad = 5 \quad (4a^2c^8)^0 \quad = 1
\]

\[
16x^6y^3 \div 4x^6y \quad 1234567^0 = 1 \quad 4ab^3 \div 4ab^3
\]

\[
= \frac{4 \cdot 16x^6y^3}{4x^6y} \quad = 4a^0b^0 \quad = a^{1-1}b^{3-3} \quad = a^0b^0 \quad = 1
\]

\[
= 4 \cdot x^0y^2 \quad = 4x^0y^2
\]

\[
= 4y^2 \quad = 4y^2
\]
The power rule

To help develop the rule, let’s consider the question below:

\[
\left(2^5\right)^3
\]

5 factors \times 5 factors \times 5 factors

altogether gives 3\times5=15 factors

\[
= 2^1 \times 2^2 \times 2^2 \times 2^2 \times 2^2 \times 2 \times 2 \times 2 \times 2 \times 2 \times 2 \times 2 \times 2 \\
= 2^{15}
\]

Generalising this:

\[
\left(a^m\right)^n = a^{m \times n}
\]

(When a power is raised to a power, multiply the exponents.)

Two more useful power rules are

\[(ab)^m = a^m b^m \text{ or } a^m b^m = (ab)^m\]

\[\left(\frac{a}{b}\right)^m = \frac{a^m}{b^m} \text{ or } \frac{a^m}{b^m} = \left(\frac{a}{b}\right)^m\]

= 5 \times 4x^{12} y^4 & = \frac{9a^8 \times 4a^3}{b^6} \times \frac{1}{b} & = 9x^4 y^6 \times 4x^3 y^{12} \\
= 20x^{12} y^4 & = \frac{36a^{8+3}}{b^{6+1}} & = 36x^{4+3} y^{6+12} \\

Topic 2: Exponent rules – integers and fraction exponents

Negative exponents

To help develop the rule, let’s consider the question below:

\[
\frac{4}{32} \quad \text{both the 4 and the 32 are powers of 2.}
\]

This question can be solved two ways: by normal fraction methods and using exponents. Because the starting question is the same, the answers must also be the same.

\[
\frac{4^1}{32^8} = \frac{1}{8} = \frac{1}{2^3}
\]

This means that:

\[
\frac{1}{2^3} = 2^{-3}
\]

Generalising this:

\[
a^{-m} = \frac{1}{a^m} \quad \text{or} \quad \frac{1}{a^{-m}} = a^m
\]

One good way to remember this rule is to say

‘Take the reciprocal and change the sign of the exponent’

Note:

There is a convention in mathematics that answers to questions should be expressed with positive exponents only.

When solving a question, use the rules in the previous section first (if possible), if an answer still contains a negative exponent then use the rule above to express with positive exponents.

Examples:
\[
\begin{align*}
3^{-4} &= \frac{1}{3^4} \quad \text{or} \quad \frac{1}{81} \\
\frac{1}{5^{-3}} &= \frac{1}{5^3} \quad \text{or} \quad 125 \\
\left(\frac{2}{7}\right)^{-2} &= \frac{49}{4}
\end{align*}
\]

\[
\begin{align*}
\frac{2^{-3}}{3^{-2}} &= \frac{3^2}{2^3} \\
&= \frac{9}{8} \quad \text{or} \quad \frac{1}{8}
\end{align*}
\]

\[
\begin{align*}
4^{-1} e^2 f^{-3} &= \frac{1}{4^1} e^2 \frac{1}{f^3} \\
&= \frac{e^2}{4f^3}
\end{align*}
\]

\[
\begin{align*}
2 \left( p^{-3}\right)^2 q^4 \times \left(4 p^2 q^{-3}\right)^{-4} &= 2 p^{-6} q^4 \times \left(2^2\right)^{-4} p^{-8} q^{-12} \\
&= 2^1 p^{-6} q^4 \times 2^{-8} p^{-8} q^{-12} \\
&= 2^{-7} p^{-14} q^{16} \\

&= x^{6} y^{-2-1} \\
&= y^{-3} \\
&= \frac{1}{y^3}
\end{align*}
\]
Fractional exponents

To help develop the rule, let’s consider the information below:

We know using exponents that:

\[
x^\frac{1}{3} \times x^\frac{1}{3} \times x^\frac{1}{3} = x^{\frac{1}{3} + \frac{1}{3} + \frac{1}{3}} = x^1 = x
\]

From the ideas about roots of numbers: \(\sqrt[3]{x} \times \sqrt[3]{x} \times \sqrt[3]{x} = x\)

That means that \(x^\frac{1}{3} = \sqrt[3]{x}\)

Generalising this:

\[
\frac{1}{n} a = \sqrt[n]{a}
\]

(This is for unit fractions)

Before proceeding with some examples, let’s have a look at the meaning of different roots.

Using Calculators

Calculators vary in the way roots are calculated.

Most calculators find square roots by: \(\text{SHIFT} \ 2 \ 5 \ \text{SHIFT} \ 5 \)

Most calculators find cube roots by: \(\text{SHIFT} \ 8 \ \text{SHIFT} \ 2 \)

To find any root, most calculators use \(\sqrt[n]{\text{num}}\)

To find \(\sqrt[4]{625}\), do \(\text{SHIFT} \ 4 \ (\text{SHIFT} \ 6) \ 2 \ 5 \ \text{SHIFT} \ 5 \)

Another option is to use the ‘raising to an exponent’ key \((^\text{x} \text{W})\) or \(\text{W}\) using the fraction or changing the fraction to a decimal: \(\sqrt[4]{625} = \left(625\right)^{\frac{1}{4}} = \left(625\right)^{0.25}\), do \(6 \ 2 \ 5 \ ^\text{x} \ 0 \ 0 \ 2 \ 5 \ \text{SHIFT} \ 5 \)

Examples:
\[
\begin{align*}
25^\frac{3}{2} &= \sqrt[2]{25} = 5 \\
256^\frac{1}{4} &= \sqrt[4]{256} = 4 \\
256^\frac{1}{4} &= (2^8)^\frac{1}{4} = 2^{8 \times \frac{1}{4}} = 2^2 \text{ or } 4
\end{align*}
\]

\[
\begin{align*}
(20)^\frac{1}{4} &= 2.115 \text{ (to 3 d.p.)} \\
&= 2.115 \text{ (to 3 d.p.)} \\
&= \left(2^n\right)^{\frac{1}{3}} = 2^{6n\times \frac{1}{3}} = \sqrt[3]{2.115} = 1.008 \text{ to 3 d.p.} \\
&= \left(1.5153\right)^{\frac{1}{52}} = \sqrt[52]{1.5153} = 8x^{\frac{1}{2}}
\end{align*}
\]

\[
\begin{align*}
\left(\frac{9}{16}\right)^\frac{1}{2} &= \sqrt{\frac{9}{16}} = \frac{3}{4} \\
(9x^4)^\frac{1}{2} &= \sqrt{9x^4} = 3x^2 \\
\sqrt{64x^{64}} &= \sqrt[64]{64} = 8x^{\frac{1}{2}}
\end{align*}
\]

\[
\begin{align*}
100^{-\frac{1}{2}} &= \frac{1}{100^\frac{1}{2}} = \frac{1}{\sqrt{100}} = \frac{1}{10} \\
\left(\frac{16x^4}{81y^8}\right)^\frac{1}{4} &= \left(\frac{2^4x^4}{3^4y^8}\right)^\frac{1}{4} = \frac{2x}{3^\frac{4}{4}y^\frac{8}{4}} = \frac{2x}{3y^2} \\
\left(\frac{16x^4}{81y^8}\right)^\frac{1}{4} &= \frac{2x}{3y^2}
\end{align*}
\]

If the exponent is a non-unit fraction, the power of a power rule can assist.

\[
\left(a^\frac{2}{3}\right) = \left(a^2\right)^\frac{1}{3} = \sqrt[3]{a^2}
\]
Generalising this:

\[
\frac{m}{a^n} = \sqrt[n]{a^m} \quad \text{or} \quad \left(\sqrt[n]{a}\right)^m
\]

Examples:

Evaluate \(\frac{2}{8^3}\)

This question can be done in three ways.

- **In the first method**, 8 is written in power form as \(2^3\) and the power of a power rule is used.

  \[
  \frac{2}{8^3} = \left(\frac{2^3}{3}\right)^{\frac{2}{3}} = 2^{\frac{2}{3}} = \sqrt[3]{2^2} = \sqrt[3]{4}
  \]

- **The second method uses a calculator with a fraction exponent.**

  \[
  \frac{2}{8^3} = \left(8^{\frac{2}{3}}\right)^{\frac{1}{3}} = \sqrt[3]{8^{\frac{2}{3}}} = 8^{\frac{2}{9}} = 8^{0.6666666666} = 4
  \]

- **The third method involves changing the fraction exponent to a decimal.**

  \[
  \frac{2}{8^3} = \left(8^{\frac{2}{3}}\right)^{\frac{1}{3}} = \sqrt[3]{8^{\frac{2}{3}}} = 8^{\frac{2}{9}} = 8^{0.6666666666} = 4
  \]

It is important to fill the display of your calculator with the recurring digit. Be careful with calculating with recurring decimals.

Evaluate \(243^{\frac{3}{5}}\)

\[
243^{\frac{3}{5}} = \left(243^{\frac{1}{3}}\right)^{\frac{3}{5}} = \left(\sqrt[3]{243}\right)^{\frac{3}{5}} = \sqrt[5]{243^{\frac{3}{5}}} = 243^{0.6} = 27
\]

or

\[
243^{\frac{3}{5}} = \left(243^{\frac{1}{3}}\right)^{\frac{3}{5}} = \left(\sqrt[3]{243}\right)^{\frac{3}{5}} = \sqrt[5]{243^{\frac{3}{5}}} = 243^{0.6} = 27
\]

Evaluate \(50^{\frac{2}{5}}\)

As 50 cannot be written in power form, only a calculator solution is possible.

\[
50^{\frac{2}{5}} = \sqrt[5]{50^2} = \sqrt[5]{5000} = 4.781762499
\]
Evaluate $128^\frac{4}{7}$

\[
128^\frac{4}{7} = \frac{1}{4} \quad 128^\frac{4}{7} = \frac{1}{\left(2^7\right)^{\frac{4}{7}}} = \frac{1}{2^4} = \frac{1}{16} \quad \text{or} \quad 0.0625
\]

Simplify $\left(625a^5b^6\right)^\frac{3}{2}$

\[
\left(625a^5b^6\right)^\frac{3}{2} = 5^{\frac{3}{2}} a^{\frac{5\times3}{2}} b^{\frac{6\times3}{2}} = 125a^\frac{15}{2}b^9
\]

Simplify $\sqrt[3]{64a^3b^5}$

\[
\sqrt[3]{64a^3b^5} = \sqrt[3]{\left(64a^3b^5\right)^{\frac{1}{3}}} = 4ab^\frac{5}{3}
\]
Simplify \( \left( \frac{625a^6}{b^8} \right)^{\frac{3}{4}} \)

\[
\left( \frac{b^8}{625a^6} \right)^{\frac{3}{4}} = \left( \frac{b^8}{5^4a^6} \right)^{\frac{3}{4}} = \frac{b^{\frac{8}{4} \times \frac{3}{4}}}{5^{\frac{4}{4} \times \frac{3}{4}}} = \frac{b^{\frac{2}{1} \times \frac{3}{4}}}{5^{1 \times \frac{3}{4}}} = \frac{b^{\frac{3}{2}}}{5^{\frac{3}{4}}} = \frac{b^{\frac{3}{2}}}{\sqrt[4]{5^3}} = \frac{b^{\frac{3}{2}}}{\sqrt[4]{125}}
\]

\[
\left( \frac{b^8}{625a^6} \right)^{\frac{3}{4}} = \left( \frac{b^8}{625^\frac{3}{2}a^6} \right)^{\frac{3}{4}} = \frac{b^{\frac{8}{3}}}{625^{\frac{3}{4}}a^6} = \frac{\sqrt[4]{625^3} b^8}{625 a^6} = \frac{125 a^6 b^8}{625 a^6} = \frac{b^8}{\sqrt[4]{125} a^6}
\]

\[
\left( \frac{b^8}{625a^6} \right)^{\frac{3}{4}} = \left( \frac{b^8}{625^\frac{3}{2}a^6} \right)^{\frac{3}{4}} = \frac{b^{\frac{8}{3}}}{625^{\frac{3}{4}}a^6} = \frac{\sqrt[4]{625^3} b^8}{625 a^6} = \frac{125 a^6 b^8}{625 a^6} = \frac{b^8}{\sqrt[4]{125} a^6}
\]

\[
\left( \frac{b^8}{625a^6} \right)^{\frac{3}{4}} = \left( \frac{b^8}{625^\frac{3}{2}a^6} \right)^{\frac{3}{4}} = \frac{b^{\frac{8}{3}}}{625^{\frac{3}{4}}a^6} = \frac{\sqrt[4]{625^3} b^8}{625 a^6} = \frac{125 a^6 b^8}{625 a^6} = \frac{b^8}{\sqrt[4]{125} a^6}
\]

Topic 3: Equations with exponents

Before starting to solve equations containing exponents, it is important to think about opposite operations just like in the Equations Topic.

You will recall the opposites below:

Revision example:

$$2x^2 + 3 = 11$$
$$2x^2 + 3 - 3 = 11 - 3 \rightarrow \text{take 3 from both sides}$$
$$2x^2 = 8$$
$$\frac{2x^2}{2} = \frac{8}{2} \rightarrow \text{divide both sides by 2}$$
$$x^2 = 4$$
$$\sqrt{x^2} = \pm\sqrt{4} \rightarrow \text{take square root of both sides}$$
$$x = \pm 2$$

There are two solutions here because both 2 and -2 satisfy the equation. This always occurs with even roots.
This list can be expanded to cubes, cube roots, to the 4, forth root, etc.

\[2x = 8 \text{ or } -6
\]
\[2x = \frac{8}{2} \text{ or } -\frac{6}{2}
\]
\[x = 4 \text{ or } -3
\]

In the question below, the opposite of raising a number to a power is raising it to the reciprocal power. Remember a number multiplied by its reciprocal gives 1.

\[x^\frac{2}{3} = 50\]
\[
\left(x^\frac{2}{3}\right)^3 = 50^\frac{3}{2}
\]
\[x = \sqrt[3]{50^\frac{3}{2}}
\]
\[x = 353.55
\]

It is also important to be able to rearrange formulae that contain powers.

Rearrange the formulae below to make the pronumeral in brackets the subject.

\[
A = \pi r^2 \quad \text{[} r \text{]}
\]
\[
\frac{A}{\pi} = r^2 \quad \text{divide both sides by} \quad \pi
\]
\[\sqrt{\frac{A}{\pi}} = \sqrt{r^2}
\]
\[r = \sqrt{\frac{A}{\pi}}
\]|\n
\[
A = \pi r^2 \quad \text{[} r \text{]}
\]
\[
\frac{A}{\pi} = r^2 \quad \text{×} \pi \quad \text{becomes} \quad \div \pi \quad \text{on LHS}
\]
\[\sqrt{\frac{A}{\pi}} = r \quad \text{becomes} \quad \sqrt{r} \quad \text{on the LHS}
\]
\[r = \sqrt[2]{\frac{A}{\pi}}
\]
The first step is to remove the fraction \( \frac{4}{3} \) by multiplying both sides by 3.

\[
3V = 4\pi r^3 \times 3 \rightarrow \text{Multiple both sides by 3}
\]

\[
3V = 4\pi r^3
\]

Divide both sides by \( 4\pi \)

\[
\frac{3V}{4\pi} = r^3
\]

\[
\sqrt[3]{\frac{3V}{4\pi}} = r
\]

\[
r = \sqrt[3]{\frac{3V}{4\pi}}
\]

---

**Or**

\[
f = \frac{1}{2\pi\sqrt{LC}} \quad \text{[C]}
\]

\[
f \times \sqrt{LC} = \frac{1}{2\pi} \times \sqrt{LC} \rightarrow \text{multiply both sides by } \sqrt{LC} \text{ to get } C \text{ into the numerator}
\]

\[
f \times \sqrt{LC} = \frac{1}{2\pi f} \rightarrow \text{divide both sides by } f
\]

\[
\left(\sqrt{LC}\right)^2 = \left(\frac{1}{2\pi f}\right)^2 \rightarrow \text{square both sides}
\]

\[
LC = \frac{1}{4\pi^2 f^2}
\]

\[
\frac{KC}{E} = \frac{1}{4\pi^2 f^2 L} \rightarrow \text{divide both sides by } L
\]

\[
C = \frac{1}{4\pi^2 f^2 L}
\]

Topic 4: Scientific notation

Scientific Notation is a way of representing numbers that are very large or very small usually to avoid writing down numbers that contain many zeros.

When numbers are written in scientific notation they usually written in this form:

\[ n \times 10^e \]

The number 4 000 000 can be written as \( 4 \times 10^6 \).

The number 0.000 8 can be written as \( \frac{8}{10^4} = 8 \times 10^{-4} \).

The number 532 000 can be written as \( 5.32 \times 10^5 \).

Mostly though, students look at the number of places that the decimal point has moved.

Writing numbers in Scientific Notation

Write 395 000 in scientific notation.

**Step 1** From your number, obtain the number between 1 and 9.999999...

\[ 395 \times 10^5 = 3.95 \times 10^5 \]

**Step 2** Calculate how many places the decimal point moved.

\[ 395 \times 10^5 = 3.95 \times 10^5 \]

The decimal point moved 5 places, so the ? becomes 5.

\[ 395 \times 10^5 = 3.95 \times 10^5 \]

**Step 3** The exponent can be positive, negative or 0. In this step, the sign of the exponent is checked.

If the original number is smaller than 1, then the exponent is negative. Otherwise it is positive or possibly zero.

Answer is \( 395 \times 10^5 \)
Write 0.000452 in scientific notation.

Topic 5: Operations with numbers in scientific notation

Multiplying

When multiplying numbers in scientific notation, the number part is multiplied and the exponent part is multiplied using exponent rules.

Example

\[
(3.1 \times 10^6) \times (1.4 \times 10^{-2}) = (3.1 \times 1.4) \times (10^6 \times 10^{-2}) \rightarrow \text{rearrange}
\]

\[
= 4.34 \times 10^4
\]

It is important to look at the solution to see if the answer is still in scientific notation.

In the example below, an adjustment is required to put the answer into scientific notation.

\[
(5.2 \times 10^{-5}) \times (3.5 \times 10^{-9}) = (5.2 \times 3.5) \times (10^{-5} \times 10^{-9}) \rightarrow \text{rearrange}
\]

\[
= 18.2 \times 10^{-5-9} = 18.2 \times 10^{-14} \rightarrow \text{The number 18.2 is not in the range 1 to 9.9999...}
\]

\[
= 1.82 \times 10^{1} \times 10^{-14} \rightarrow 18.2 = 1.82 \times 10^{1}
\]

\[
= 1.82 \times 10^{1-14} = 1.82 \times 10^{-13}
\]

The speed of light is approximately \(3 \times 10^8 \text{ m/sec}\). How far will it travel in 5 hours?

5 hours
= 5 \times 60 \text{ minutes}
= 5 \times 60 \times 60 \text{ seconds}
= 18000 \text{ seconds}
= 1.8 \times 10^4 \text{seconds}

Distance covered = speed \times time
\[
= (3 \times 10^8) \times (1.8 \times 10^4)
\]

\[
= 5.4 \times 10^{12} \text{ metres}
\]
Dividing

Dividing numbers in scientific notation is similar to multiplication. The number part is divided as usual and the exponent part is divided using exponent rules.

Example:

\[
\frac{6.25 \times 10^7}{5.1 \times 10^{-2}} = (6.25 \div 5.1) \times (10^7 \div 10^{-2}) = 1.2255 \times 10^{7-(-2)} = 1.2255 \times 10^9
\]

As in multiplying, it is important to look at the solution to see if the answer is still in scientific notation.

In the example below, an adjustment is required to put the answer into scientific notation.

\[
\frac{3.12 \times 10^{-7}}{7.36 \times 10^4} = (3.12 \div 7.36) \times (10^{-7} \div 10^4) = 0.4239 \times 10^{-7-4} = 0.4239 \times 10^{-11} \to \text{The number 0.4239 is not in the range 1 to 9.9999...},
\]

\[
= 4.239 \times 10^{-1} \times 10^{-11} \to 0.4239 = 4.239 \times 10^{-1}
\]

\[
= 4.239 \times 10^{-12}
\]

The mass of a hydrogen atom is \(1.6 \times 10^{-24}\) grams. How many atoms are there in 1 mg (1 \(\times 10^{-3}\) gram) of hydrogen?

Number of atoms \(= \frac{1 \times 10^{-3}}{1.6 \times 10^{-24}} = (1 \div 1.6) \times (10^{-3} \div 10^{-24}) = 0.625 \times 10^{3-(-24)} = 0.625 \times 10^{21} = 6.25 \times 10^2\times 10^{21} = 6.25 \times 10^{20}\)
Adding and Subtracting

When adding or subtracting any numbers, it is important that numbers of the same place value are added or subtracted. When adding or subtracting whole numbers or decimals these means lining up the numbers in place value rows.

With numbers written in scientific notation, lining up numbers in place values is achieved by having exponent parts the same.

Add \((3 \times 10^5)\) and \((4 \times 10^7)\)

\[
\begin{align*}
(3 \times 10^5) + (4 \times 10^7) &= 3 \times 10^{-2} \times 10^7 + 4 \times 10^7 \\
&= 0.03 \times 10^7 + 4 \times 10^7 \\
&\rightarrow \text{Both numbers are in the same place value} \\
&= 4.03 \times 10^7
\end{align*}
\]

One exponent must be changed to be the same as the other exponent. Choosing the higher exponent makes the finding then solution slightly easier.

Take \(4.3 \times 10^4\) from \(1.95 \times 10^3\)

\[
\begin{align*}
1.95 \times 10^3 - 4.3 \times 10^4 &= 1.95 \times 10^{-1} \times 10^4 - 4.3 \times 10^4 \\
&= 0.195 \times 10^3 - 4.3 \times 10^4 \\
&= (0.195 - 4.3) \times 10^4 \\
&= -4.105 \times 10^4
\end{align*}
\]

The largest number is negative \(\rightarrow\) answer is negative \(\rightarrow\) \(-4.105\)

Add \(3.652 \times 10^{-4}\) and \(4.2 \times 10^{-7}\)

\[
\begin{align*}
3.652 \times 10^{-4} + 4.2 \times 10^{-7} &= 3.652 \times 10^{-4} + 4.2 \times 10^{-3} \times 10^{-4} \\
&= 3.652 \times 10^{-4} + 0.0042 \times 10^{-4} \\
&= (3.652 + 0.0042) \times 10^{-4} \\
&= 3.6562 \times 10^{-4}
\end{align*}
\]

Remember \(-4\) is larger than \(-7\).
Calculator use

To use scientific notation on your calculator, some calculators have a key marked $\text{Exp}$, others $\text{K}$.

$2 \times 10^{11}$ is entered by the sequence: $2 \times \text{10}^{11}$ or $2 \text{Exp}11$

$4.25 \times 10^{-6}$ is entered by the sequence $4 \times 2.5 \times \text{10}^{-6}$ or $4 \times 2.5 \text{Exp}(-6)$

$-8.75 \times 10^{15}$ is entered by the sequence $-8 \times 7.5 \times \text{10}^{15}$

$-1.6 \times 10^{-19}$ is entered by the sequence $-1 \times 6 \times \text{10}^{-19}$

If you enter a number expressed in scientific notation using $\text{Exp}$ or the $\times \text{10}$ keys, the calculator treats this as a single number (which it is) ☑.

However, if you enter your number using the $\text{G}$ key, for example $2\text{G}11$, the calculator treats this as two numbers being multiplied and this can lead to incorrect answers when performing calculations ☠.

Using your calculator to change between scientific notation and standard notation can be quite difficult. If you require this you will need to obtain the instructions for your calculator and find out how to achieve this.

Performing an operation such as $2 \times 10^{11} \times 4.25 \times 10^{-6}$ is entered as:

$2\times\text{10}^{11} \times 4 \times 2.5 \times \text{10}^{-6} = 850000$

The format of your answer will vary from calculator to calculator. Because the answer to this question is able to be displayed on a calculator in standard notation, the answer displayed could be 850 000, so you have to change this to $8.5 \times 10^5$ if you specifically need the answer in scientific notation. Other calculators may automatically give the answer in scientific notation. If numbers are outside the range of what can be displayed in standard form on the calculator, your calculator should display the answer in scientific notation. Even when using a calculator, it is still important to be able to change from standard form to scientific notation and vice-versa.
